1   Solution via matrix multiplication

The problem from YouTube video "Olympiad level counting - How many subsets of $\{1,\ldots,2000\}$ have a sum divisible by 5" by 3Blue1Brown (url: https://www.youtube.com/watch?v=bOXCLR3Wric) can be described via matrix multiplication.

We want to name the counts of sums congruent to (0, 1, …, d-1) modulo d (d=5 in the video) as $c_0, c_1, \cdots c_{d-1}$.

As per definition in video, an empty set has a sum of 0 and is a multiple of d.

If we know the counts $c_0, c_1, \cdots c_{d-1}$ in a set of given numbers (set C), and we've got another set with counts $a_0, a_1, \cdots a_{d-1}$ (set A), the total counts $t_0, t_1, \cdots t_{d-1}$ for the union (set T) of these two sets will be (e. g. d=5):

$$\begin{pmatrix} t_0 \\ t_1 \\ t_2 \\ t_3 \\ t_4 \end{pmatrix} = \begin{pmatrix} c_0 & c_4 & c_3 & c_2 & c_1 \\ c_1 & c_0 & c_4 & c_3 & c_2 \\ c_2 & c_1 & c_0 & c_4 & c_3 \\ c_3 & c_2 & c_1 & c_0 & c_4 \\ c_4 & c_3 & c_2 & c_1 & c_0 \end{pmatrix} \cdot \begin{pmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \\ a_4 \end{pmatrix} \quad .$$

For example, for the count of sums congruent to 2 in the new set T, we can combine:
- sums congruent to 2 from set C and sums congruent to 0 from set A,
- sums congruent to 1 from set C and sums congruent to 1 from set A,
- sums congruent to 0 from set C and sums congruent to 2 from set A,
- sums congruent to 4 from set C and sums congruent to 3 from set A, and
- sums congruent to 3 from set C and sums congruent to 4 from set A.

In total, it will be $c_2 \cdot a_0 + c_1 \cdot a_1 + c_0 \cdot a_2 + c_4 \cdot a_3 + c_3 \cdot a_4$, which is third row (t_2) from the result of matrix multiplication.

1.1   Calculation for any number

First of all, we know that for an empty set, there is one sum (= 0), so c_0 is 1 and $c_1 = c_2 = c_3 = c_4 = 0$.

Then we combine this set with a set with only the number "1". We've got two possibilities here to:

- either don't use the new number (congruent 0 mod 5, a_0=1), or

- or use the new number (congruent 1 mod 5, $a_1=1$).

So for the new set as union of empty set and number "1", we've got the following new counts in a solution vector.

$$\begin{pmatrix} t_0 \\ t_1 \\ t_2 \\ t_3 \\ t_4 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} \quad .$$

It works similarly when combining this set with number "2":

$$\begin{pmatrix} t_0 \\ t_1 \\ t_2 \\ t_3 \\ t_4 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 \\ 0 \\ 1 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 0 \end{pmatrix} \quad .$$

For sets with 3, 4, and 5 numbers:

$$n=3: \begin{pmatrix} t_0 \\ t_1 \\ t_2 \\ t_3 \\ t_4 \end{pmatrix} = \begin{pmatrix} 2 \\ 2 \\ 1 \\ 2 \\ 1 \end{pmatrix}, n=4: \begin{pmatrix} t_0 \\ t_1 \\ t_2 \\ t_3 \\ t_4 \end{pmatrix} = \begin{pmatrix} 4 \\ 3 \\ 3 \\ 3 \\ 3 \end{pmatrix}, n=5: \begin{pmatrix} t_0 \\ t_1 \\ t_2 \\ t_3 \\ t_4 \end{pmatrix} = \begin{pmatrix} 8 \\ 6 \\ 6 \\ 6 \\ 6 \end{pmatrix} \quad .$$

For sets with numbers $n > 5$, we can repeat the matrix generation and matrix multiplication with the solution vector for n=5. If there is remainder for n divided by 5, we will apply another matrix multiplication with solution vector of n=1, …, 4.

For n = 2000, we will need 2000 / 5 = 400 steps.

But we can also calculate solution vectors for $n=5^1$, 5^2, 5^4, etc. by multiplying the generated matrix with the new solution vector coming out from the matrix multiplication.
For n = 2000 = 5 * 400 and 400 = 1 1001 0000$_b$, we need to multiply with solution vectors of 5^{16}, 5^{128}, and 5^{256}.

2 Solution via generating function

In the YouTube video "Olympiad level counting - How many subsets of {1,…,2000} have a sum divisible by 5" by 3Blue1Brown (url: https://www.youtube.com/watch?v=bOXCLR3Wric), it shows a solution by using a generating function:

$$f(x)=(1+x)(1+x^2)(1+x^3)...(1+x^{2000})$$
$$f(x)=\sum_{n=0}^{N} c_n x^n = 1+x+x^2+2x^3+2x^4+... \quad .$$

With $\zeta = e^{\frac{2\pi i}{5}}$, the sum f($\zeta^0$)+f($\zeta^1$)+f($\zeta^2$)+f($\zeta^3$)+f($\zeta^4$) results in 5 times of the sum of coefficients which is multiple of 5:

$$f\left(\xi^0\right)+f\left(\xi^1\right)+f\left(\xi^2\right)+f\left(\xi^3\right)+f\left(\xi^4\right)=5\cdot\left(c_0+c_5+c_{10}+...\right)$$

For numbers n which is multiple of 5, the video gives the answer that there are $\frac{1}{5}\left(2^n+4\cdot2^{\frac{n}{5}}\right)$ sums

which are divisible by 5. E. g. for n=2000, there are $\frac{1}{5}\left(2^{2000}+4\cdot2^{400}\right)$ of them.

This approach works similarly with every divisor d >= 2 and when n is multiple of d.

2.1   Calculation for remainder of sums other than 0

I've have modified this approach by adding factors while adding the generating functions. With $\alpha_{l,k}=\zeta^{k(d-l)}$ and k is the remainder of sums when dividing by d (e. g. 5), the sum $\alpha_{0,k}$f(ζ^0)+$\alpha_{1,k}$f(ζ^1)+$\alpha_{2,k}$f(ζ^2)+$\alpha_{3,k}$f(ζ^3)+$\alpha_{4,k}$f(ζ^4) results in 5 times of the sum of coefficients with remainders is k = (0, …, 4) when divided by 5:

$$k=0:\alpha_{0,0}f\left(\xi^0\right)+\alpha_{1,0}f\left(\xi^1\right)+\alpha_{2,0}f\left(\xi^2\right)+\alpha_{3,0}f\left(\xi^3\right)+\alpha_{4,0}f\left(\xi^4\right)=5\cdot\left(c_0+c_5+c_{10}+...\right)$$
$$k=1:\alpha_{0,1}f\left(\xi^0\right)+\alpha_{1,1}f\left(\xi^1\right)+\alpha_{2,1}f\left(\xi^2\right)+\alpha_{3,1}f\left(\xi^3\right)+\alpha_{4,1}f\left(\xi^4\right)=5\cdot\left(c_1+c_6+c_{11}+...\right)$$
$$k=2:\alpha_{0,2}f\left(\xi^0\right)+\alpha_{1,2}f\left(\xi^1\right)+\alpha_{2,2}f\left(\xi^2\right)+\alpha_{3,2}f\left(\xi^3\right)+\alpha_{4,2}f\left(\xi^4\right)=5\cdot\left(c_2+c_7+c_{12}+...\right)$$
$$k=3:\alpha_{0,3}f\left(\xi^0\right)+\alpha_{1,3}f\left(\xi^1\right)+\alpha_{2,3}f\left(\xi^2\right)+\alpha_{3,3}f\left(\xi^3\right)+\alpha_{4,3}f\left(\xi^4\right)=5\cdot\left(c_3+c_8+c_{13}+...\right)$$
$$k=4:\alpha_{0,4}f\left(\xi^0\right)+\alpha_{1,4}f\left(\xi^1\right)+\alpha_{2,4}f\left(\xi^2\right)+\alpha_{3,4}f\left(\xi^3\right)+\alpha_{4,4}f\left(\xi^4\right)=5\cdot\left(c_4+c_9+c_{14}+...\right)$$

For k=0, the formula $\frac{1}{5}\left(2^n+4\cdot2^{\frac{n}{5}}\right)$ remains the same since all factors $\alpha_{l,0}$ equal to 1. For

k=1..4, we've got the formula $\frac{1}{5}\left(2^n-2^{\frac{n}{5}}\right)$ for number of sums with remainder k when divided by

5.

This approach works similarly with every divisor d >= 2 and when n is multiple of d. If n is not a multiple of d, we'll have to apply matrix multiplication with solution vector of n=1, …, d-1 (see 1.1).
